Abstract

USE OF PHOTONIC BAND GAP STRUCTURES IN OPTICAL AMPLIFIERS

An optical amplifier uses a photonic band gap structure having a doped core defining at least a first wavelength range over which stimulated emission can occur after excitation caused by the introduction of pump light. photonic band gap structure is designed to permit light having energy corresponding to the wavelength range to be 10 transmitted only in selected directions, including along the photonic band gap structure. The propagation down the structure is one of a discrete number of possible transmission directions for the photons resulting from This improves the pump efficiency, stimulated emission. 15 as the stimulated emissions are concentrated into the direction of propagation down the fiber.
